

SFDA SAFETY SIGNAL

“A signal is defined by the SFDA as reported information on a possible causal relationship between an adverse event and a drug, the relationship being unknown or incompletely documented previously. Usually more than a single report is required to generate a signal, depending upon the seriousness of the event and the quality of the information. A signal is a hypothesis together with data and arguments and it is important to note that a signal is not only uncertain but also preliminary in nature”

Saudi Food and Drug Authority (SFDA) – Safety Signal of Bisoprolol and the Risk of Acute kidney injury

*The Saudi Food and Drug Authority (SFDA) recommends all health care professionals to be aware of the safety signal of **Acute kidney injury** associated with the use of **Bisoprolol**. The signal has been originated as a result of routine pharmacovigilance monitoring activities.*

Introduction

Bisoprolol is a medication used to manage and treat hypertension and congestive heart failure. The drug belongs to the selective beta-blocker class of drugs and acts explicitly as a cardioselective beta1-blocker (B1-blocker).^[1] Acute kidney injury, previously known as acute renal failure, denotes a sudden and often reversible reduction in kidney function, as measured by increased creatinine or decreased urine volume.^[2] The aim of this review is to evaluate the risk of Acute kidney injury associated with the use of Bisoprolol and to suggest regulatory recommendations if required.

Methodology

Signal Detection team at SFDA performed a signal review using National Pharmacovigilance Center (NPC) database, and World Health Organization (WHO) database, VigiBase, with literature screening to retrieve all related information to assess the causality between Acute kidney injury and Bisoprolol use. The search conducted on June 2024.

Results

Case Review: Signal detection team at SFDA have searched Saudi national database and WHO database to find individual case safety reports (ICSRs). The WHO database resulted in 481 global case-reports while only one local case found. The authors used signal detection tool (Vigilyze) to retrieve all reported global cases.^[3] Authors also applied WHO-UMC causality assessment criteria on the 30 extracted ICSRs with highest completeness score.^[4] Among them, 23 cases were probably and possibly linked to Bisoprolol, and 1 cases assessed as not assessable due to lack of important information, while the remaining 6 cases assessed as unlikely.

Datamining: The disproportionality of the observed and the expected reporting rate for drug/adverse drug reaction pair is estimated using information component (IC), a tool developed by WHO-UMC to measure the reporting ratio. Positive IC reflects higher statistical association while negative values indicates less statistical association. The IC result is (2.0) for this drug/ADR combination which reflects positive statistical association. ^[4]

Conclusion

The weighted cumulative evidence identified from assessed cases and disproportionality analysis are suggestive for causal association between Bisoprolol and Acute kidney injury. Health care professionals and health regulators must be aware of the potential risk in drug recipients.

Report Adverse Drug Events (ADRs) to the SFDA

The SFDA urges both healthcare professionals and patients to continue reporting adverse drug reactions (ADRs) resulted from using any medications to the SFDA either online, by regular mail or by fax, using the following contact information:

National Pharmacovigilance Center (NPC)
Saudi Food and Drug Authority-Drug sector
